Abstract. Objective measurement of fatigability in patients with neurological diseases remains a problem rarely described in the research. The quick and easy assessment of muscle fatigue among patients with multiple sclerosis (MS) is a needed tool, which could be implemented as a standard test among those patients, to better plan and conduct physiotherapy. New devices, such as Luna EMG, allows to create precise environment, to carry out objective assessment and providing data based on strength and electromyography (EMG) measurement, especially median frequency (MDF), which is the standard parameter to indicate fatigue. The experiment was performed among 25 MS patients. Subjects were asked to perform 5 minutes isokinetic exercise of elbow flexion and extension and 2 minutes of isokinetic exercise of the same joint, with a 2 min break between. RMS value, median of frequency and its slope during exercise, was assessed for biceps and triceps brachii. The mean strength of both muscles were measured at the same time, accompanied by the automated counting of repetition. The correlation concerning triceps brachii has been found, between the amount of repetition in first exercise, with the slope of frequency in the first exercise (5 minutes isokinetic exercise). The same correlation for triceps brachii has been found for the second isokinetic exercise (2 minutes isokinetic exercise). For biceps brachii different correlation has occurred. The correlation between amount of repetition in 5 minutes isokinetic exercise and the slope in second (2 minutes) exercise has been noted. The mean strength during flexion for 5 minutes exercise was 11.20 Nm and 9.5 for extension. During 2 minutes exercise the mean values were 11.53 Nm and 10.18 Nm respectively. Assessment of MS patients performed with the usage of newest devices allows us to observe muscle fatigue, strength, muscle activation and relations between them among patients with MS. This quick test, accompanied by functional assessment can be a base for patient objective evaluation and a good foundation for planning and controlling training, in terms of muscle fatigue, applied force, muscle activation and coordination.

Keywords: sclerosis multiplex (MS), fatigue, exercise, sEMG

3.1.Luna EMG

3.1.1. Assessment of Muscle Fatigue, Strength and Muscle Activation During Exercises with the Usage of Robot Luna EMG, Among Patients with Multiple Sclerosis.

Goal:

The main goal of the study was to create and test a special protocol, using innovative device, such as Luna EMG, to assess fatigue and other related factors among patients with multiple sclerosis.

Conclusion:

Technologies can provide valid, reliable and sensitive assessment tools that, when used alongside clinical measures, can inform clinical decision-making and provide richer data on patient outcomes. There is now a clear need for guidelines for clinicians and researchers to optimize technology-based assessment and application of clinical measures and procedures.

List of publications

3.1.2. The Influence of EMG-Triggered Robotic Movement on Walking, Muscle Force and Spasticity after an Ischemic Stroke.

Goal:

The aim of the study was to determine the effect of electromyographic triggering (EMG-triggered) robotic rehabilitation device treatment on walking, muscle force, and spasticity after an ischemic stroke.

Conclusion:

Using EMG triggered therapy in rehabilitation of stroke patients provides a possibility to learn how to use these preserved pathways. After a treatment, a patient is able to better control the muscle tone. This accelerates the motor function recovery, which allows for regaining the functional efficiency after a stroke.

Abstract: Cerebral amyloid angiopathy (CAA) is one form of disease of the small vessels of the brain and can cause frequent cerebral hemorrhages as well as other types of stroke. The aim of the study was to analyze the static and dynamic balance of the body and changes in the tension of selected muscles of the cervical spine in patients with CAA after stroke, depending on visual control or its absence, compared to healthy volunteers. Eight stroke patients and eight healthy subjects were examined. The functional Unterberger test and the Biodex SD platform were used to test the dynamic equilibrium, on which the static equilibrium was also assessed. Muscle tension was tested with the Luna EMG device. In static tests, the LC muscle (longus colli) was significantly more active with and without visual control ($p = 0.016$; $p = 0.002$), and in dynamic tests, significantly higher results for MOS ($p = 0.046$) were noted. The comparison of the groups led to the conclusion that the more functional deficits, the more difficult it is to keep balance, also with eye control.

Keywords: stroke; CAA (Cerebral Amyloid Angiopathy); balance; muscle tension; vision

1. Introduction

Cerebral amyloid angiopathy (CAA) is one of the forms of diseases of the small vessels of the brain. It causes the deposition of β -amyloid protein in the wall of arterioles, capillaries and venous vessels located in the cerebral cortex and the soft dura. The prevalence of CAA is very age dependent. From 2.3 percent in patients aged 65 to 74 years, from 12.1 percent in patients aged 85 and over [1]. Cerebral amyloid angiopathy is asymptomatic or with symptoms such as intracerebral hemorrhage, cognitive impairment or dementia [2,3]. Similar to Alzheimer’s disease, it is a degenerative disease of the group of diseases called amyloidopathy. It is a disease of old age and is the second most common (after atherosclerosis) cause of recurrent cerebral haemorrhages [4–18]. CAA is relatively most common in the occipital, frontal, temporal and parietal lobes. The cerebellum is most rarely involved, and it is practically absent in the basal ganglia, thalamus, white matter and brainstem. CAA is characterized by a variable course and a chronically progressive disease process [19,20].

In our work, we present a group of stroke patients diagnosed with CAA. Stroke as well as other neurological conditions such as Alzheimer’s disease, Parkinson’s disease and syndrome, peripheral neuropathies, epilepsy, migraine, multiple sclerosis, etc., are disorders related to imbalance. It should also be remembered that aging has a large effect on the equilibrium system [7,21,22].

Balance disorders are one of the most common problems in adults (affecting 20–30% of the population) [23–25]. Of this, women and people from the geriatric group report the problem twice as often [26,27].

3.1.3. The Relationship between the Static and Dynamic Balance of the Body, the Influence of Eyesight and Muscle Tension in the Cervical Spine in CAA Patients—A Pilot Study.

Goal:

The aim of the study was to assess the ability to maintain static and dynamic balance of the body and the distribution of muscle tension in the cervical spine, depending on the eye control, in CAA patients and healthy volunteers.

Conclusion:

The Luna EMG rehabilitation device was used to assess muscle tone. Eyesight plays an important role in controlling the balance. especially in healthy. The more functional deficits the more difficult it is to restore balance also with eye control.

3.1.4. Influence of the Passive Stabilization of the Trunk and Upper Limb on selected Parameters of the Hand Motor Coordination, Grip Strength and Muscle Tension, in Post-Stroke Patients.

Goal:

The aim of the study was to evaluate the influence of the stable position of the trunk and upper limb on the parameters of hand and wrist movement coordination, grip strength and muscle tension in subacute post-stroke patients compared to healthy subjects. The aim of the study was also to evaluate the parameters of the affected upper limb depending on whether the examined limb was dominant or non-dominant.

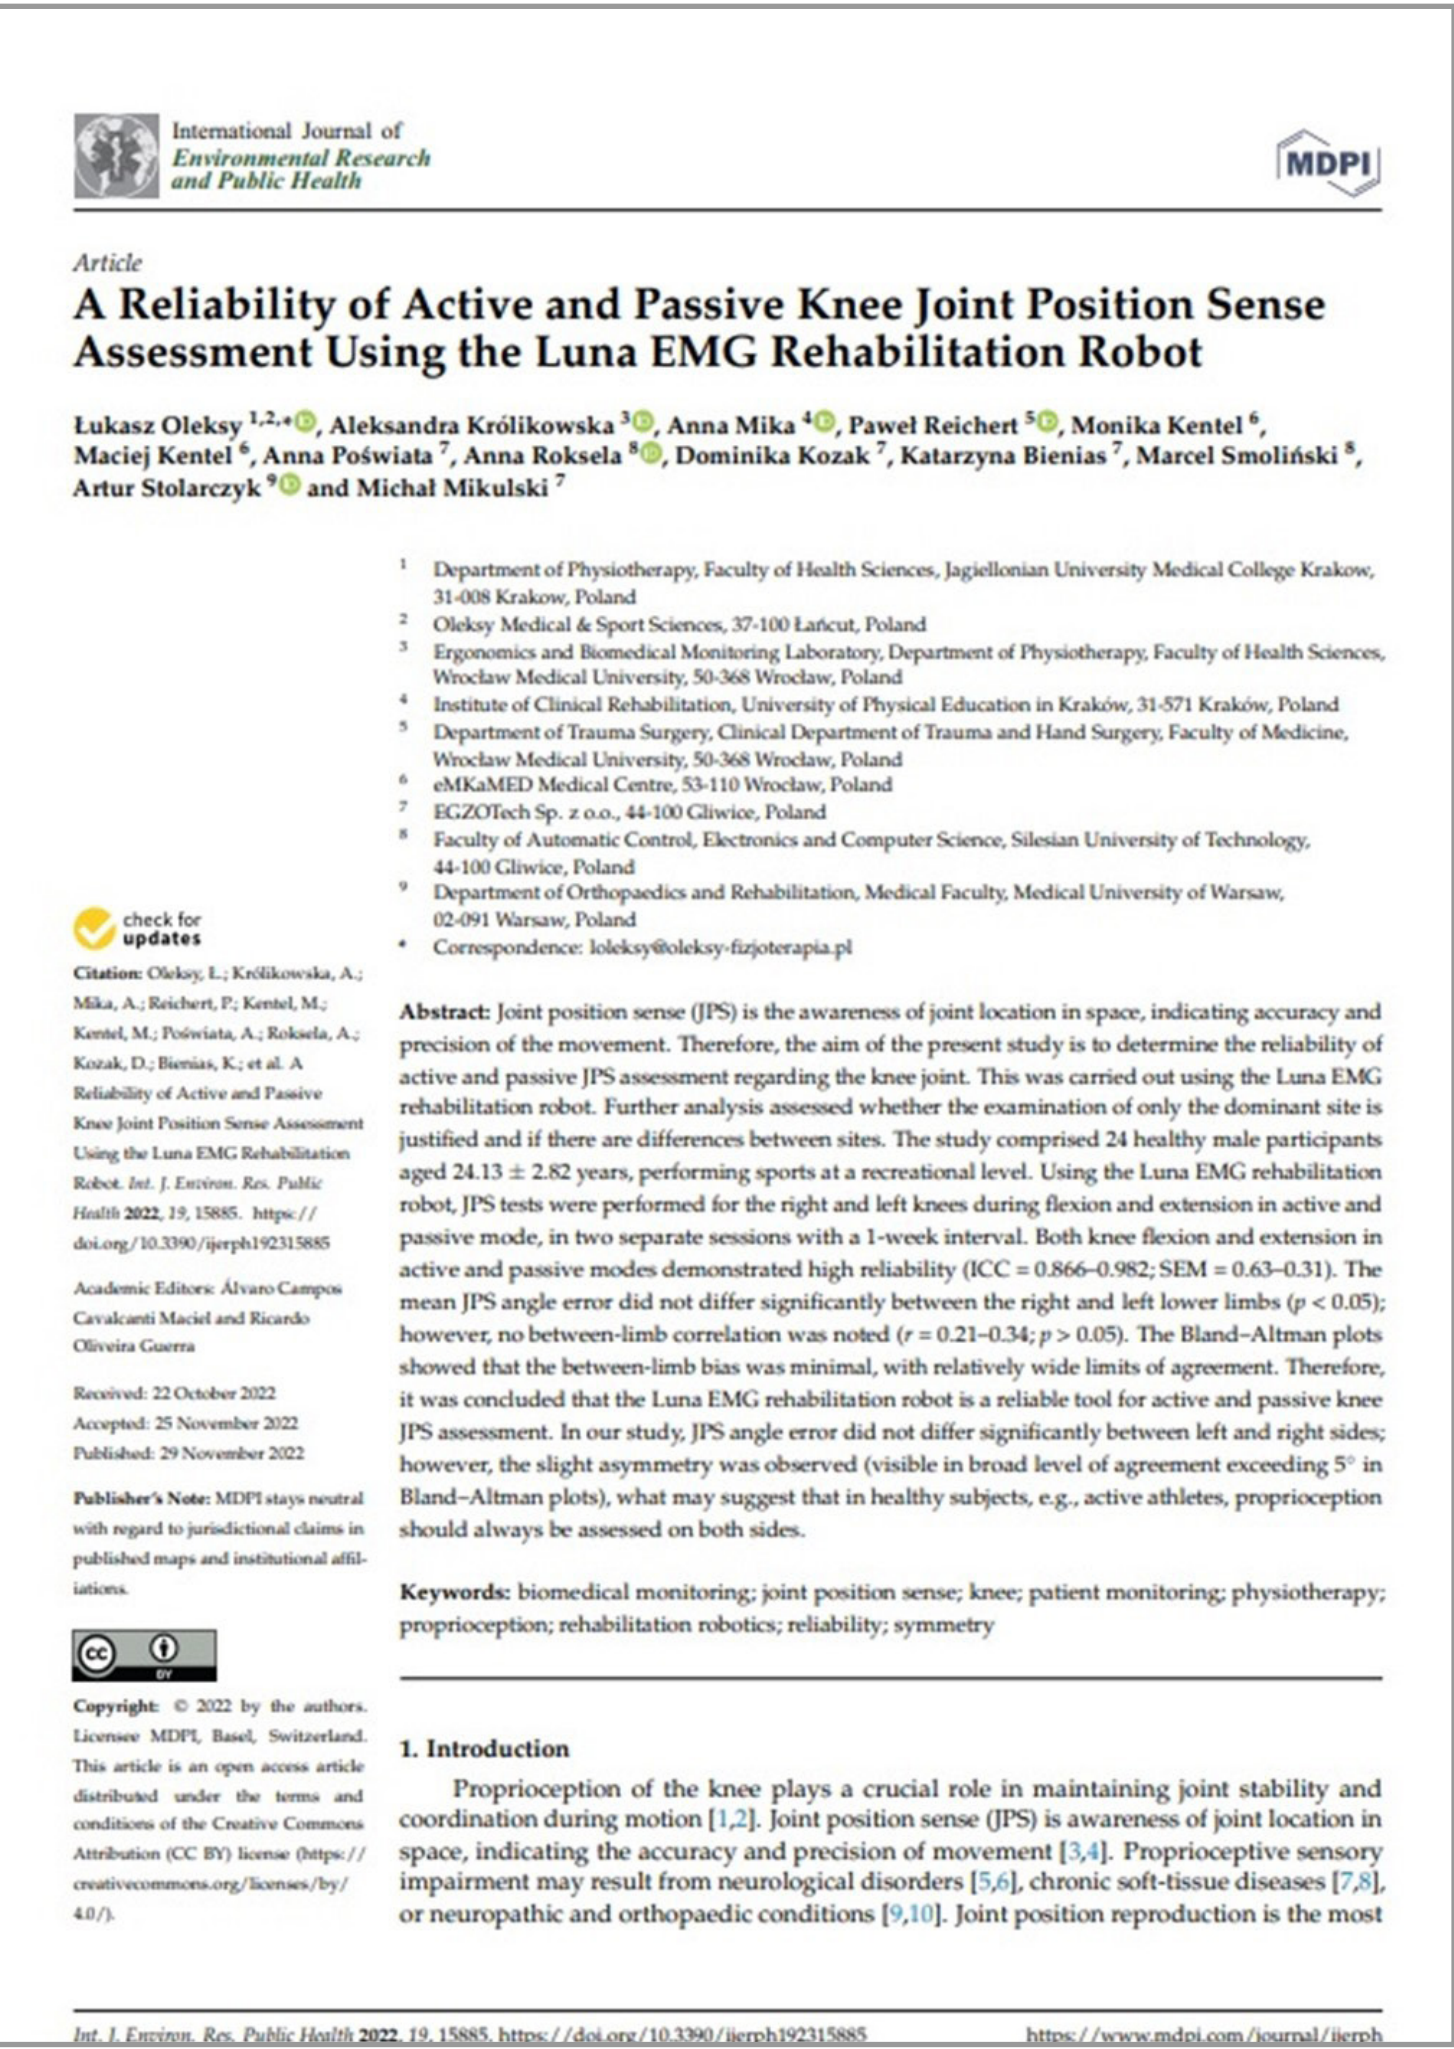

Conclusion:

Study found that passive stabilization of the shoulder in addition to the trunk during stroke rehabilitation is important to restore the correct movement pattern and regain function of the hand.

3.1.5. A Reliability of Active and Passive Knee Joint Position Sense Assessment using the Luna EMG Rehabilitation Robot.

Goal:

The aim of the study was to determine the reliability of active and passive JPS assessment in the knee joint using the Luna EMG rehabilitation robot. As the second aim, this study is the first to assess whether examining only the dominant limb is justified and if there are any between-limb differences in either active or passive modes.

Conclusion:

Luna EMG rehabilitation robot is a reliable tool for JPS assessment in both knee flexion and extension, in active and passive modes as well on the right as on the left sides.

List of publications

3.1.6. Importance of core stability for coordinated movement of the human body in stroke rehabilitation.

Goal:

The aim of the study was to examine the effect of core stability on parameters of coordinated movement of the trunk and lower extremities in post-stroke rehabilitation.

Conclusion:

Muscle tensions were generally lower in post-stroke patients compared to those with lower back pain syndrome but active abdominal tension muscles caused the increase of core stability and alter the trunk movement path, and improves gait and range of movement. Core stability training during stroke rehabilitation may help patients to achieve a higher level of coordinated movement.

Abstract: This pilot study aimed to assess the safety and feasibility of an EMG-driven rehabilitation robot in patients with Post-Viral Fatigue (PVF) syndrome after COVID-19. The participants were randomly assigned to two groups (IG—intervention group and CG—control group) in an inpatient neurological rehabilitation unit. Both groups were assessed on admission and after six weeks of rehabilitation. Rehabilitation was carried out six days a week for six weeks. The patients in the IG performed additional training using an EMG rehabilitation robot. Muscle fatigue was assessed using an EMG rehabilitation robot; secondary outcomes were changes in hand grip strength, Fatigue Assessment Scale, and functional assessment scales (Functional Independence Measure, Barthel Index). Both groups improved in terms of the majority of measured parameters comparing pre- and post-intervention results, except muscle fatigue. Muscle fatigue scores presented non-significant improvement in the IG and non-significant deterioration in the CG. Using an EMG rehabilitation robot in patients with PVF can be feasible and safe. To ascertain the effectiveness of such interventions, more studies are needed, particularly involving a larger sample and also assessing the participants' cognitive performance.

Keywords: SARS-CoV-2; exercises; physiotherapy; occupational therapy; hand grip strength

1. Introduction

COVID-19 is a condition caused by a novel severe acute respiratory syndrome, which has been known for the last two years. A SARS-CoV-2 infection manifests itself through a wide spectrum of symptoms, from asymptomatic to life-threatening and possibly, fatal [1–6]. The course of a SARS-CoV-2 infection is highly individual. Most patients recover completely; however, approximately 20% experience long-term adverse effects, including fatigue (58%), headaches (44%), cognitive impairment (27%), excessive hair loss (25%), and dyspnoea (24%) [7]. Fatigue is one of the most common effects of COVID-19 [2] and can still exist days after the first symptom of this condition [8,9]. According to the World Health Organization International Classification of Diseases for Mortality and Morbidity Statistics, 11th Revision (ICD-11), Post-Viral Fatigue (PVF) is a neurological condition; the definition of PVF includes chronic fatigue syndrome and myalgic encephalomyelitis [10]. With similar symptoms characterizing both chronic fatigue syndrome and myalgic encephalomyelitis, and with no clear knowledge about their pathogenesis and no consensus in terms of medical treatment, grouping these conditions under the definition of PVF helps

3.1.7. Application of an EMG-Rehabilitation Robot in Patients with Post-Coronavirus Fatigue Syndrome (COVID-19)—A Feasibility Study.

Goal:

The aim of the study was to assess the safety and feasibility of the use of an EMG-Rehabilitation Robot in exercises performed by Post-COVID patients with PVF.

Conclusion:

The study demonstrated that implementing an EMG robot-rehabilitation protocol in PVF patients is feasible and safe. In this pilot study, the feasibility of the concept of using the EMG—rehabilitation robot in exercises for patients with PVF syndrome was verified positively.

Abstract: The aim of this study was to compare the effectiveness of traditional neurological rehabilitation and neurological rehabilitation combined with a rehabilitation robot for patients with post-COVID-19 fatigue syndrome. Eighty-six participants transferred from intensive care units due to post-viral fatigue after COVID-19 were randomly divided into two groups: the intervention group and the control group. The control group received standard neurological rehabilitation for 120 min a day, while the intervention group received the same neurological rehabilitation for 75 min a day, complemented by 45 min of exercises on the rehabilitation robot. The Berg scale, Tinetti scale, six-minute walking test, isokinetic muscle force test, hand grip strength, Barthel Index, and Functional Independence Measure were used to measure the outcomes. Both groups improved similarly during the rehabilitation. Between groups, a comparison of before/after changes revealed that the intervention group improved better in terms of Functional Independence Measure ($p = 0.015$) and mean extensor strength ($p = 0.023$). The use of EMG-driven robots in the rehabilitation of post-COVID-19 fatigue syndrome patients was shown to be effective.

1. Introduction

In recent years, a new global health problem emerged due to the novel coronavirus—SARS-CoV-2—causing coronavirus disease 2019 (COVID-19). This virus, which first appeared in China, has quickly spread worldwide, causing a global pandemic. In addition to the characteristic symptoms of respiratory tract infections, such as fever, cough, or fatigue, in the course of COVID-19, many other symptoms are likely to appear, including loss of taste and smell, sore throat, headache, muscle or joint pain, skin rash, nausea and vomiting, and dizziness [1]. In the vast majority of cases, the course of the disease is mild (80%), according to the WHO. However, some patients require hospitalization, and the condition might even lead to death. Importantly, not only the course of COVID-19 constituted a public health problem [2]. It is estimated that up to 20% of patients who had recovered suffered from long-term complications after contracting COVID-19 [3,4], which was also observed in patients with a mild course of the disease [5].

A similar phenomenon has also been reported for other viral diseases. Tansey et al. [6] showed that in the case of the SARS-CoV-1 virus epidemic, which took place in 2003, over half of the patients discharged from hospitals after treatment of the disease developed fatigue syndrome. Among the respondents, as many as 64% experienced fatigue after

3.1.8. The Effect of Using a Rehabilitation Robot for Patients with Post-Coronavirus Disease (COVID-19) Fatigue Syndrome.

Goal:

The aim of this study was to compare the effectiveness of traditional neurological rehabilitation against neurological rehabilitation combined with a rehabilitation robot for patients with post-COVID-19 fatigue syndrome.

Conclusion:

In light of the results of the present study, implementing EMG-driven robots in the rehabilitation of post-COVID-19 fatigue syndrome patients is effective. Substituting a part of traditional rehabilitation with robotic rehabilitation did not negatively alter rehabilitation outcomes. Our results indicate that the implementation of robotic rehabilitation for patients with post-coronavirus fatigue syndrome in rehabilitation programs can be supported.

Abstract. Diagnosing neurological disorders and tracking rehabilitation progress requires objective, quantitative measures. Isokinetic exercises are commonly employed to evaluate muscle strength and activity. However, repetitive, quantitative assessment of the tests performed during these exercises can be difficult, especially for patients with neurological disorders. Usually, either dynamometric or sEMG measurements are used. This study is concerned with the evaluation of the applicability and reliability of these two measurement techniques, based on analysis of elbow flexion and extension supported by the Luna EMG rehabilitation robot, aimed at the evaluation of the activity of the biceps and triceps muscles. Dynamometric and surface electromyography measurements are compared with respect to their repeatability between sessions and days, and their ability to differentiate impaired limbs from healthy ones.

Keywords: rehabilitation robotics, neurological disorders, electromyography, dynamometry, isokinetic tests

1 Introduction

Stroke is ranked as the second leading cause of death worldwide, however, the high morbidity also results in 50 % of survivors suffering from chronic disability [1]. One of the most important areas affected by stroke is motor skills. Precise, sensitive muscle strength and activity testing methods are needed to evaluate muscle functioning in patients with neurological disorders. Biomedical engineering provides valid, reliable, and sensitive evaluation tools that, when used alongside clinical measures, can support clinical decision-making and supply richer

3.1.9. Evaluation of Neurological Disorders in Isokinetic Dynamometry and Surface Electromyography Activity of Biceps and Triceps Muscles.

Goal:

Study is concerned with the evaluation of the applicability and reliability of these two measurement techniques, based on analysis of elbow flexion and extension supported by the Luna EMG rehabilitation robot, aimed at the evaluation of the activity of the biceps and triceps muscles.

Conclusion:

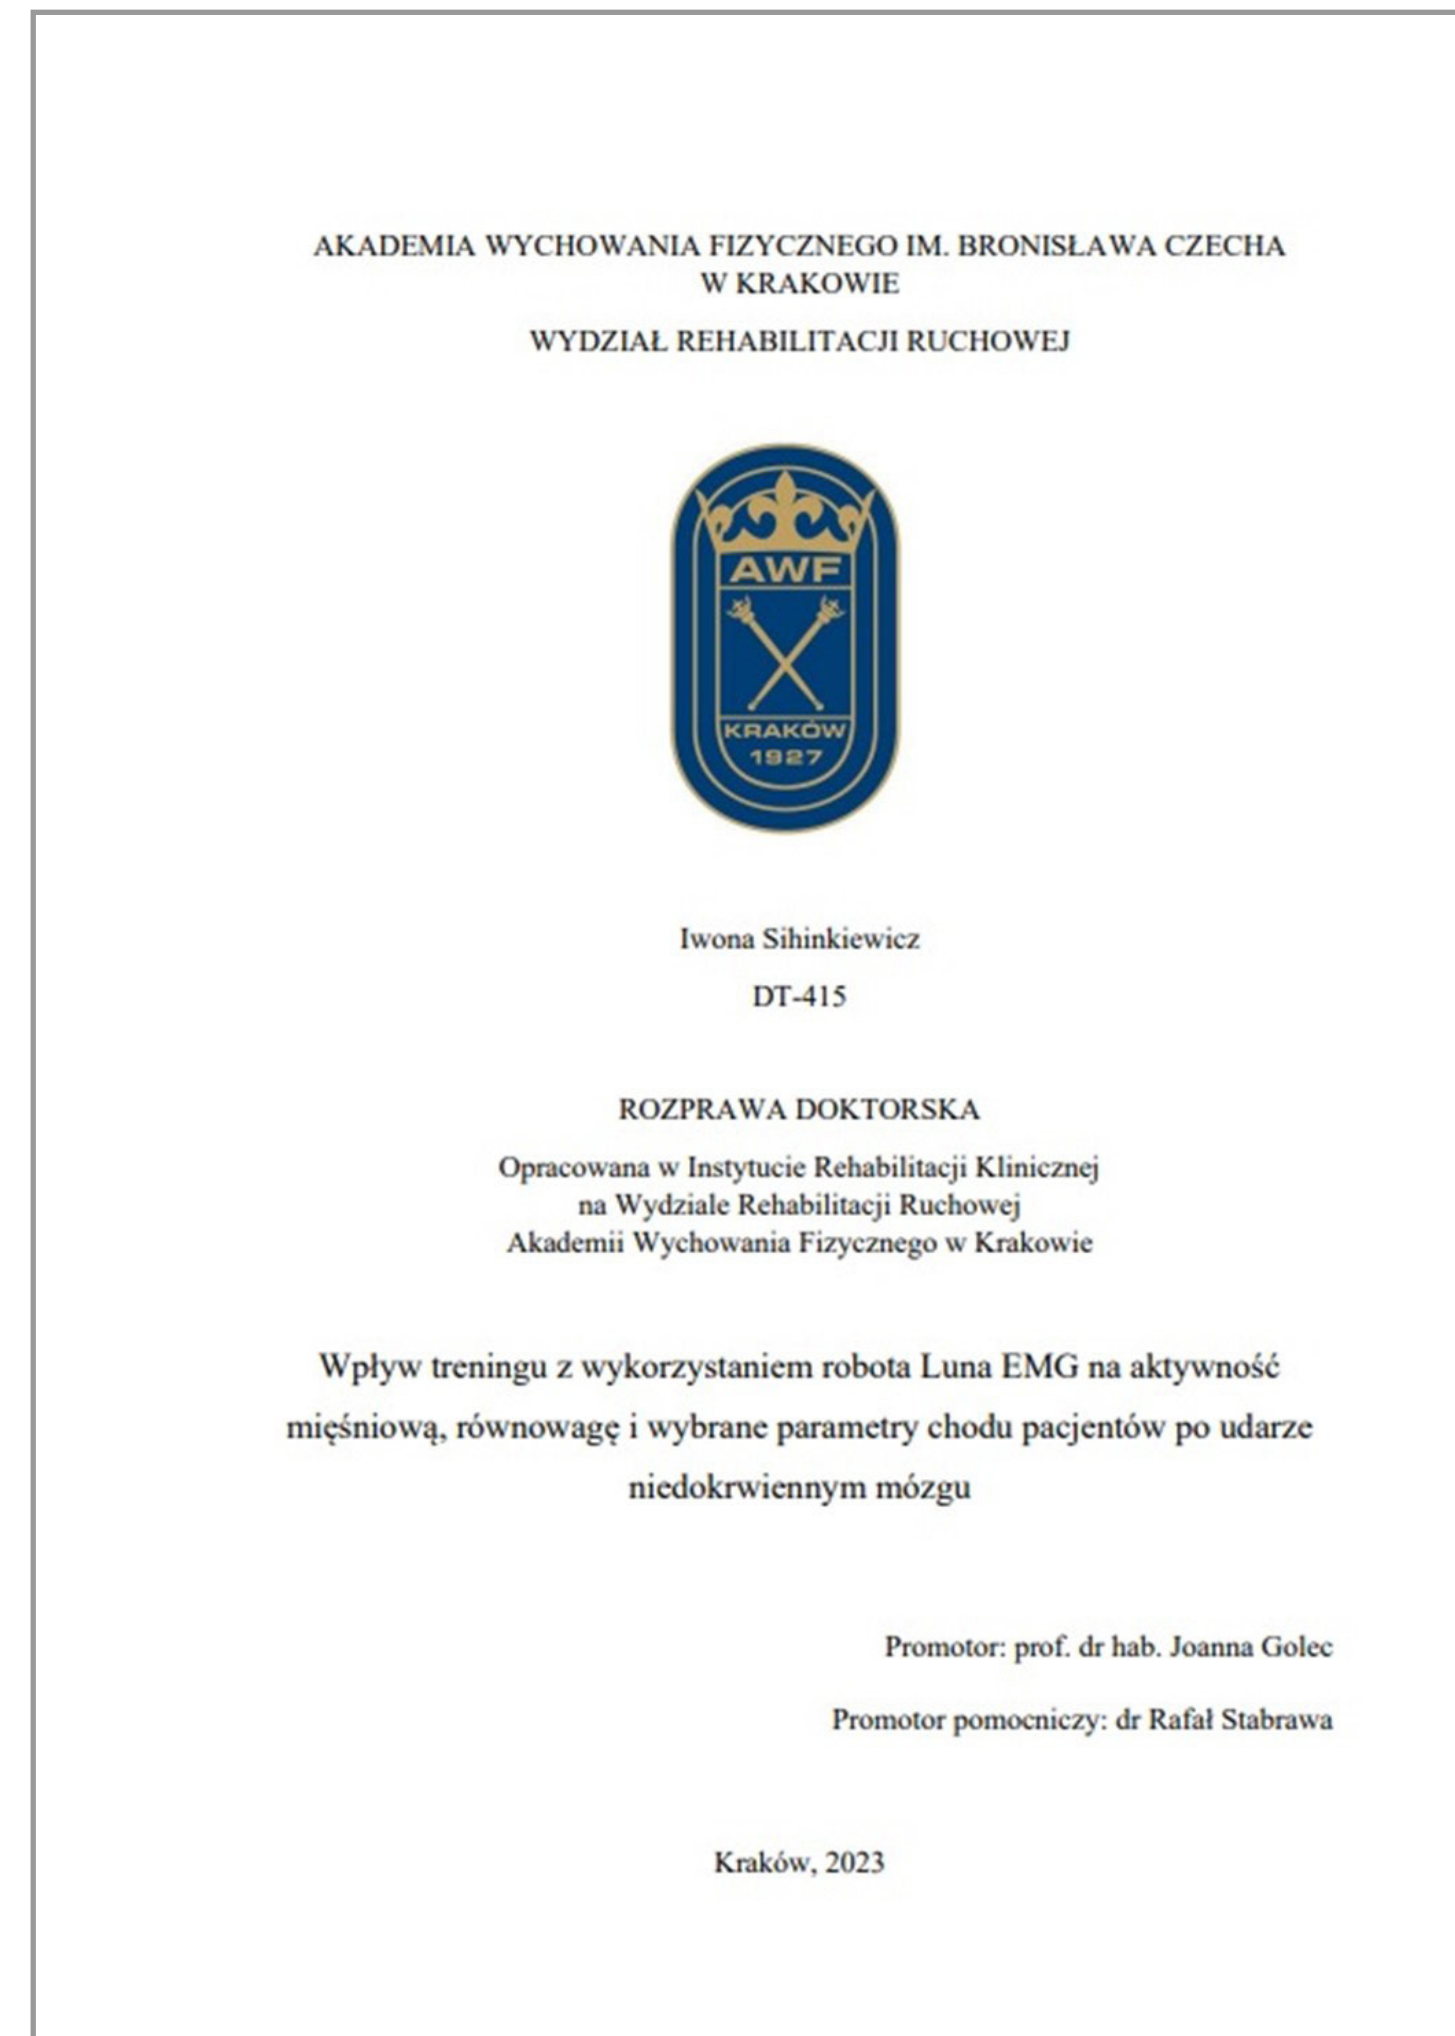

Study has highlighted the promise and challenges of using the isokinetic dynamometry and surface electromyography test to evaluate muscle strength and activity. Isokinetic testing with a rehabilitation robot, facilitating both types of measurements is recommended to provide outcome measures for the progress evaluation of neurological disorders, valuable for clinicians.

3.1.10. The impact of training with the Luna EMG usage on muscle activity, balance and selected gait parameters of patients after ischemic stroke.

Goal:

The aim of the study was to assess the impact of affected lower limb training using the Luna EMG on muscle activity, balance and gait speed of patients after ischemic stroke.

Conclusion:

The addition of the affected lower limb training using reactive electromyography, with the Luna EMG, to the commonly used rehabilitation program, allows to obtain significant functional improvement in patients after ischemic stroke. The usage of innovative technology in the commonly used rehabilitation program for patients after ischemic stroke allows to achieve effective therapy, with less physical burden on the physiotherapist.

Systematyczny przegląd piśmiennictwa dotyczący wykorzystania robotów EMG w rehabilitacji kończyny dolnej u osób po udarze mózgu

Streszczenie

Udar mózgu jest powszechnym problemem zdrowotnym na całym świecie, często powodującym deficyty kończyn dolnych i stanowiącym znaczne wyzwanie dla fizjoterapeutów w zakresie rehabilitacji chodu. Wraz z postępem technologicznym, opracowano nowe narzędzia rehabilitacyjne, takie jak roboty sterowane za pomocą elektromiografii (EMG). Jednakże, ze względu na ich wysoki koszt, konieczne jest zbadanie ich skuteczności w rehabilitacji. W związku z tym celem tej pracy było określenie skuteczności terapii z wykorzystaniem robotów sterowanych EMG w porów-

3.1.11. Systematic Review of EMG-Driven Robots in Lower Extremity Post-Stroke Rehabilitation.

Goal:

The aim of this review was to investigate the current literature on the effectiveness of EMG-driven robots for gait management in the physiotherapy treatment of stroke patients. The research question was: “In adult poststroke hemiparetic patients, what is the effect of EMG-driven robots on gait rehabilitation compared to conventional physiotherapy training (CPT)?”.

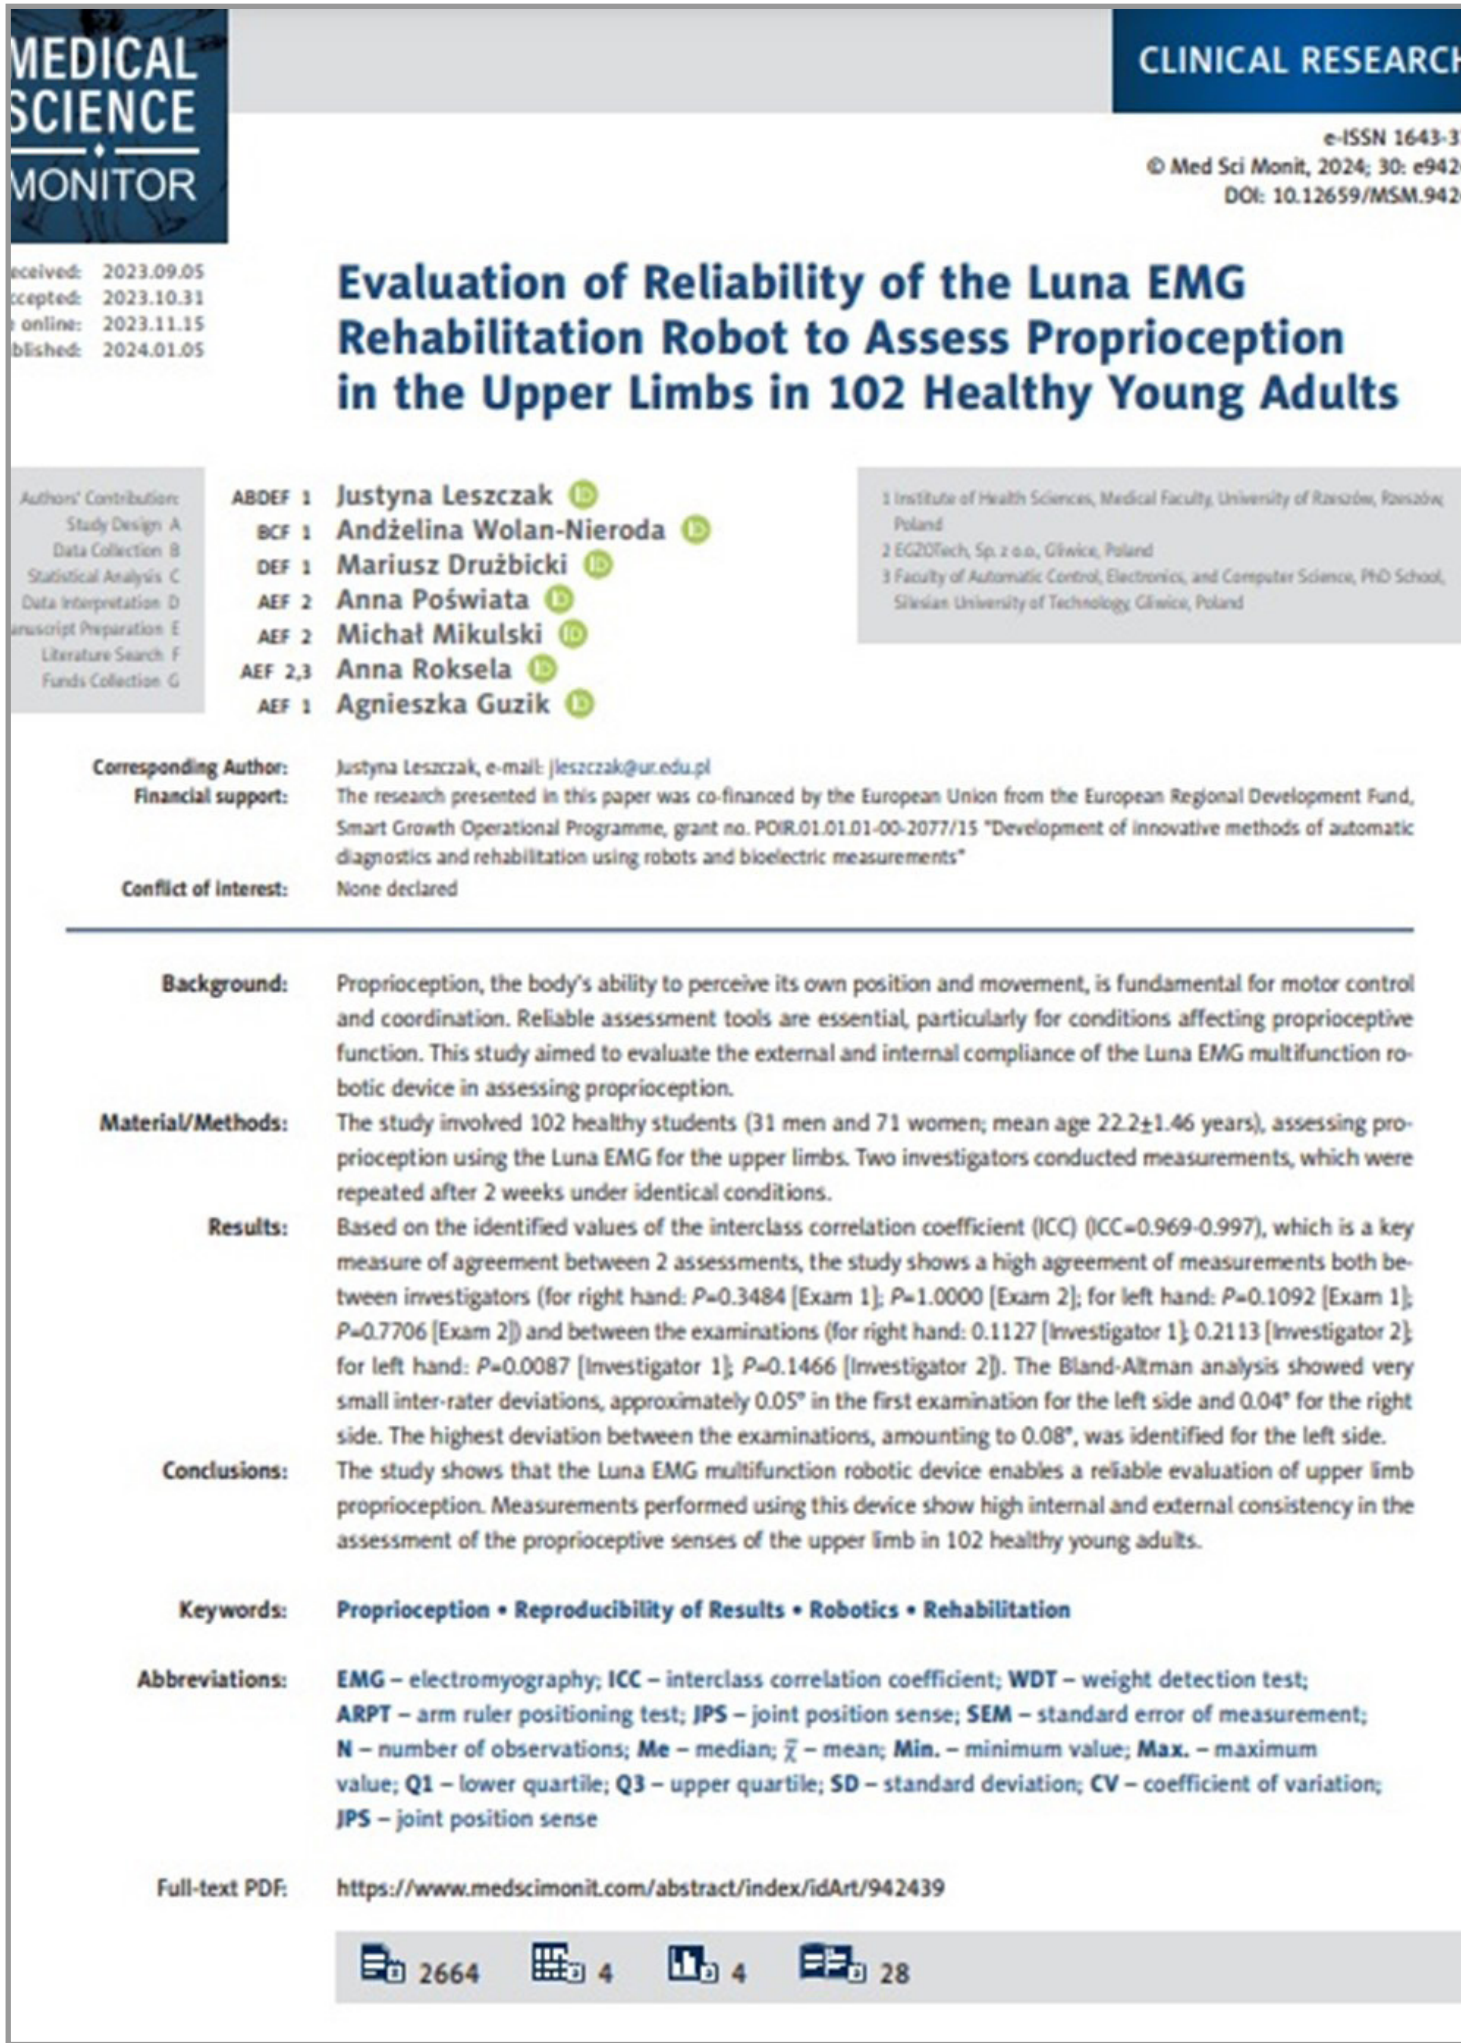

Conclusion:

In summary, no relevant conclusion can be drawn about the effectiveness of EMG-driven robots alone for post-stroke patients’ gait in comparison with conventional physiotherapy training, but it seems that a mixed approach combining both of them could be the most beneficial.

3.1.12. Evaluation of Reliability of the Luna EMG Rehabilitation Robot to Assess Proprioception in the Upper Limbs in 102 Healthy Young Adults.

Goal:

The study aimed to examine external and internal compliance (ie, inter- and intrarater reliability) of the Luna EMG multifunction robotic device as a tool to assess upper-limb proprioception.

Conclusion:

The Luna EMG multifunction robotic device is a reliable tool in the evaluation of upper-limb proprioception. Measurements made with the Luna EMG show high internal and external consistency in assessment of the proprioceptive senses of the upper limbs in a group of 102 healthy young adults.

3.1.14. Effectiveness of robotic rehabilitation in improving muscular strength and mobility in patients with multiple sclerosis.

Goal:

The aim of this study was to assess the effects of the LUNA-EMG rehabilitation robot (RR) on muscular strength, balance, and gait in patients with multiple sclerosis (MS).

Conclusion:

The results of this study demonstrate that the use of the RR led to significant improvements in muscular strength among MS patients, particularly in the quadriceps and hamstring muscles. However, no significant differences were observed in balance, gait, quality of life, or proprioception between the RR group and the control group. These findings suggest that robot-assisted rehabilitation, as facilitated by the LUNA-EMG robot, holds promise as a method for enhancing muscular strength in MS patients. Further research with a larger sample size is warranted to confirm these findings and to explore additional outcomes.

List of publications

3.1.15. LUNA EMG as a Marker of Adherence to Prehabilitation Programs and Its Effect on Postoperative Outcomes among Patients Undergoing Cytoreductive Surgery for Ovarian Cancer and Suspected Ovarian Tumors.

Goal:

The aim of the study is to assess the impact of multimodal preparation in the prehabilitation protocol on the incidence of postoperative complications and duration of hospitalization after surgery among women scheduled for cytoreductive surgery due to advanced-stage ovarian cancer. The second aim is to evaluate if LUNA EMG might serve as a useful tool to assess patient compliance with a prehabilitation protocol.

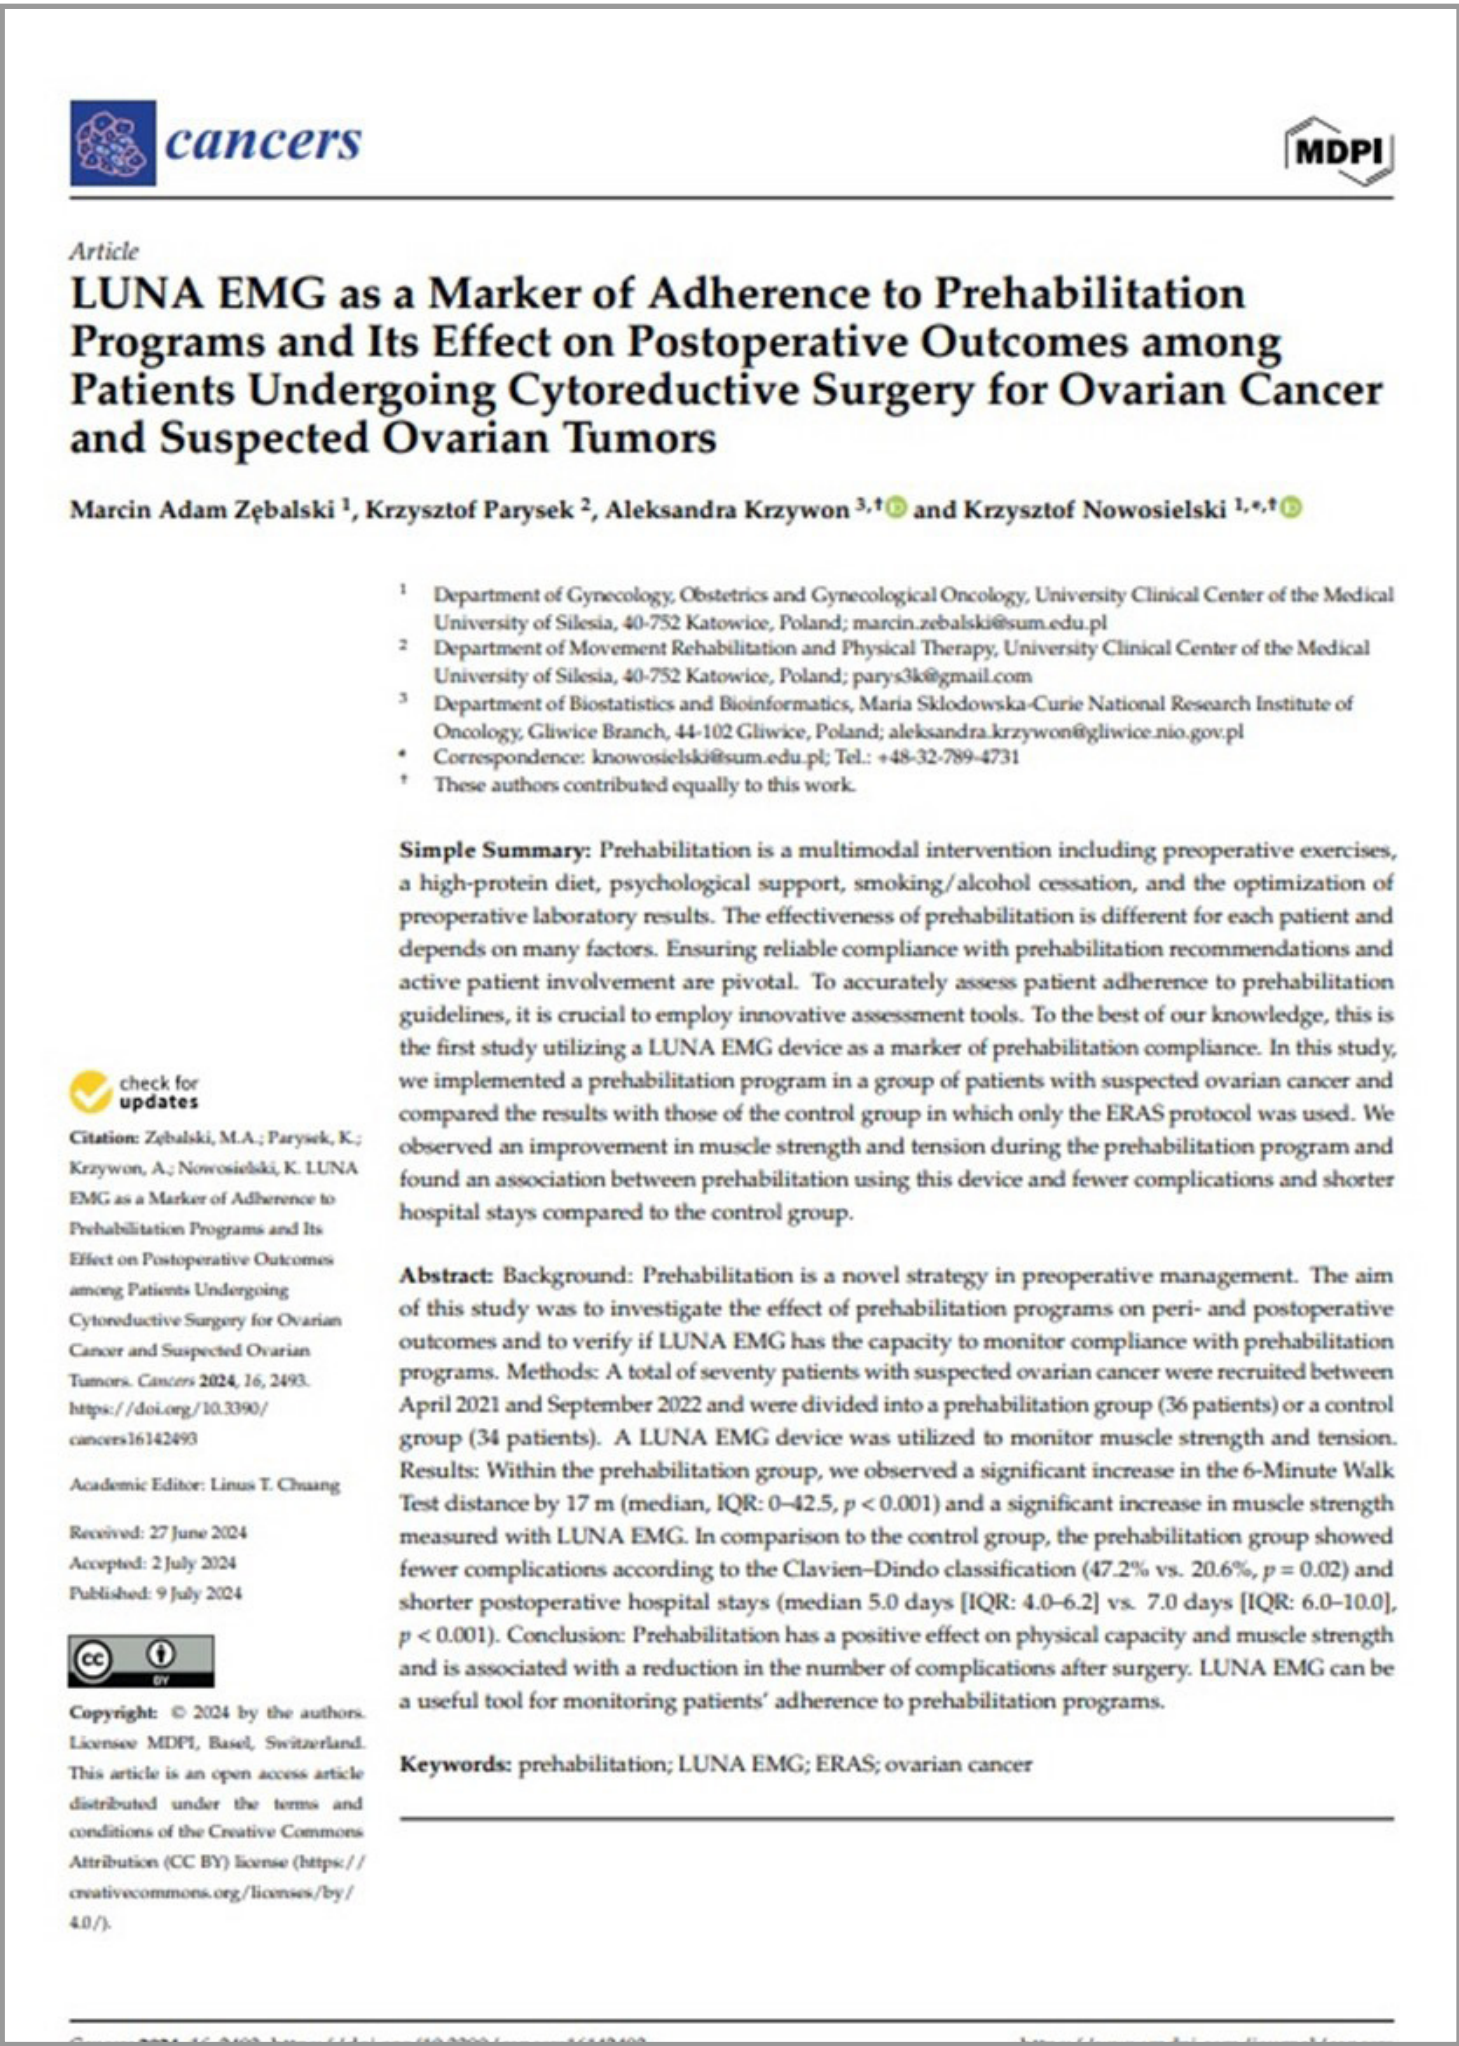

Conclusion:

The prehabilitation program proposed in this study improves muscle strength and physical performance, which reduces the number of postoperative complications and shortens the length of hospital stays. Testing muscle tension with the LUNA EMG device can be a useful tool for monitoring the progress of physical preparation.

Cit.:

Zębalski, MA, Parysek K, Krzywón, A, Nowosielski K. *LUNA EMG as a Marker of Adherence to Prehabilitation Programs and Its Effect on Postoperative Outcomes among Patients Undergoing Cytoreductive Surgery for Ovarian Cancer and Suspected Ovarian Tumors*. *Cancers* 2024, 16(14), 2493; <https://www.mdpi.com/2072-6694/16/14/2493>

List of publications

3.1.16. Surface electromyography vs clinical outcome measures after robot-assisted gait training in patients with spinal cord injury after post-acute phase of rehabilitation.

Goal:

The aim of the study was to evaluate the usefulness of sEMG for outcome measures in patients with subacute SCI who underwent RAGT, compared with those who underwent DPT. A secondary aim was to correlate sEMG changes with clinical status, as tested using functional scales (including spasticity) and muscle strength testing.

Conclusion:

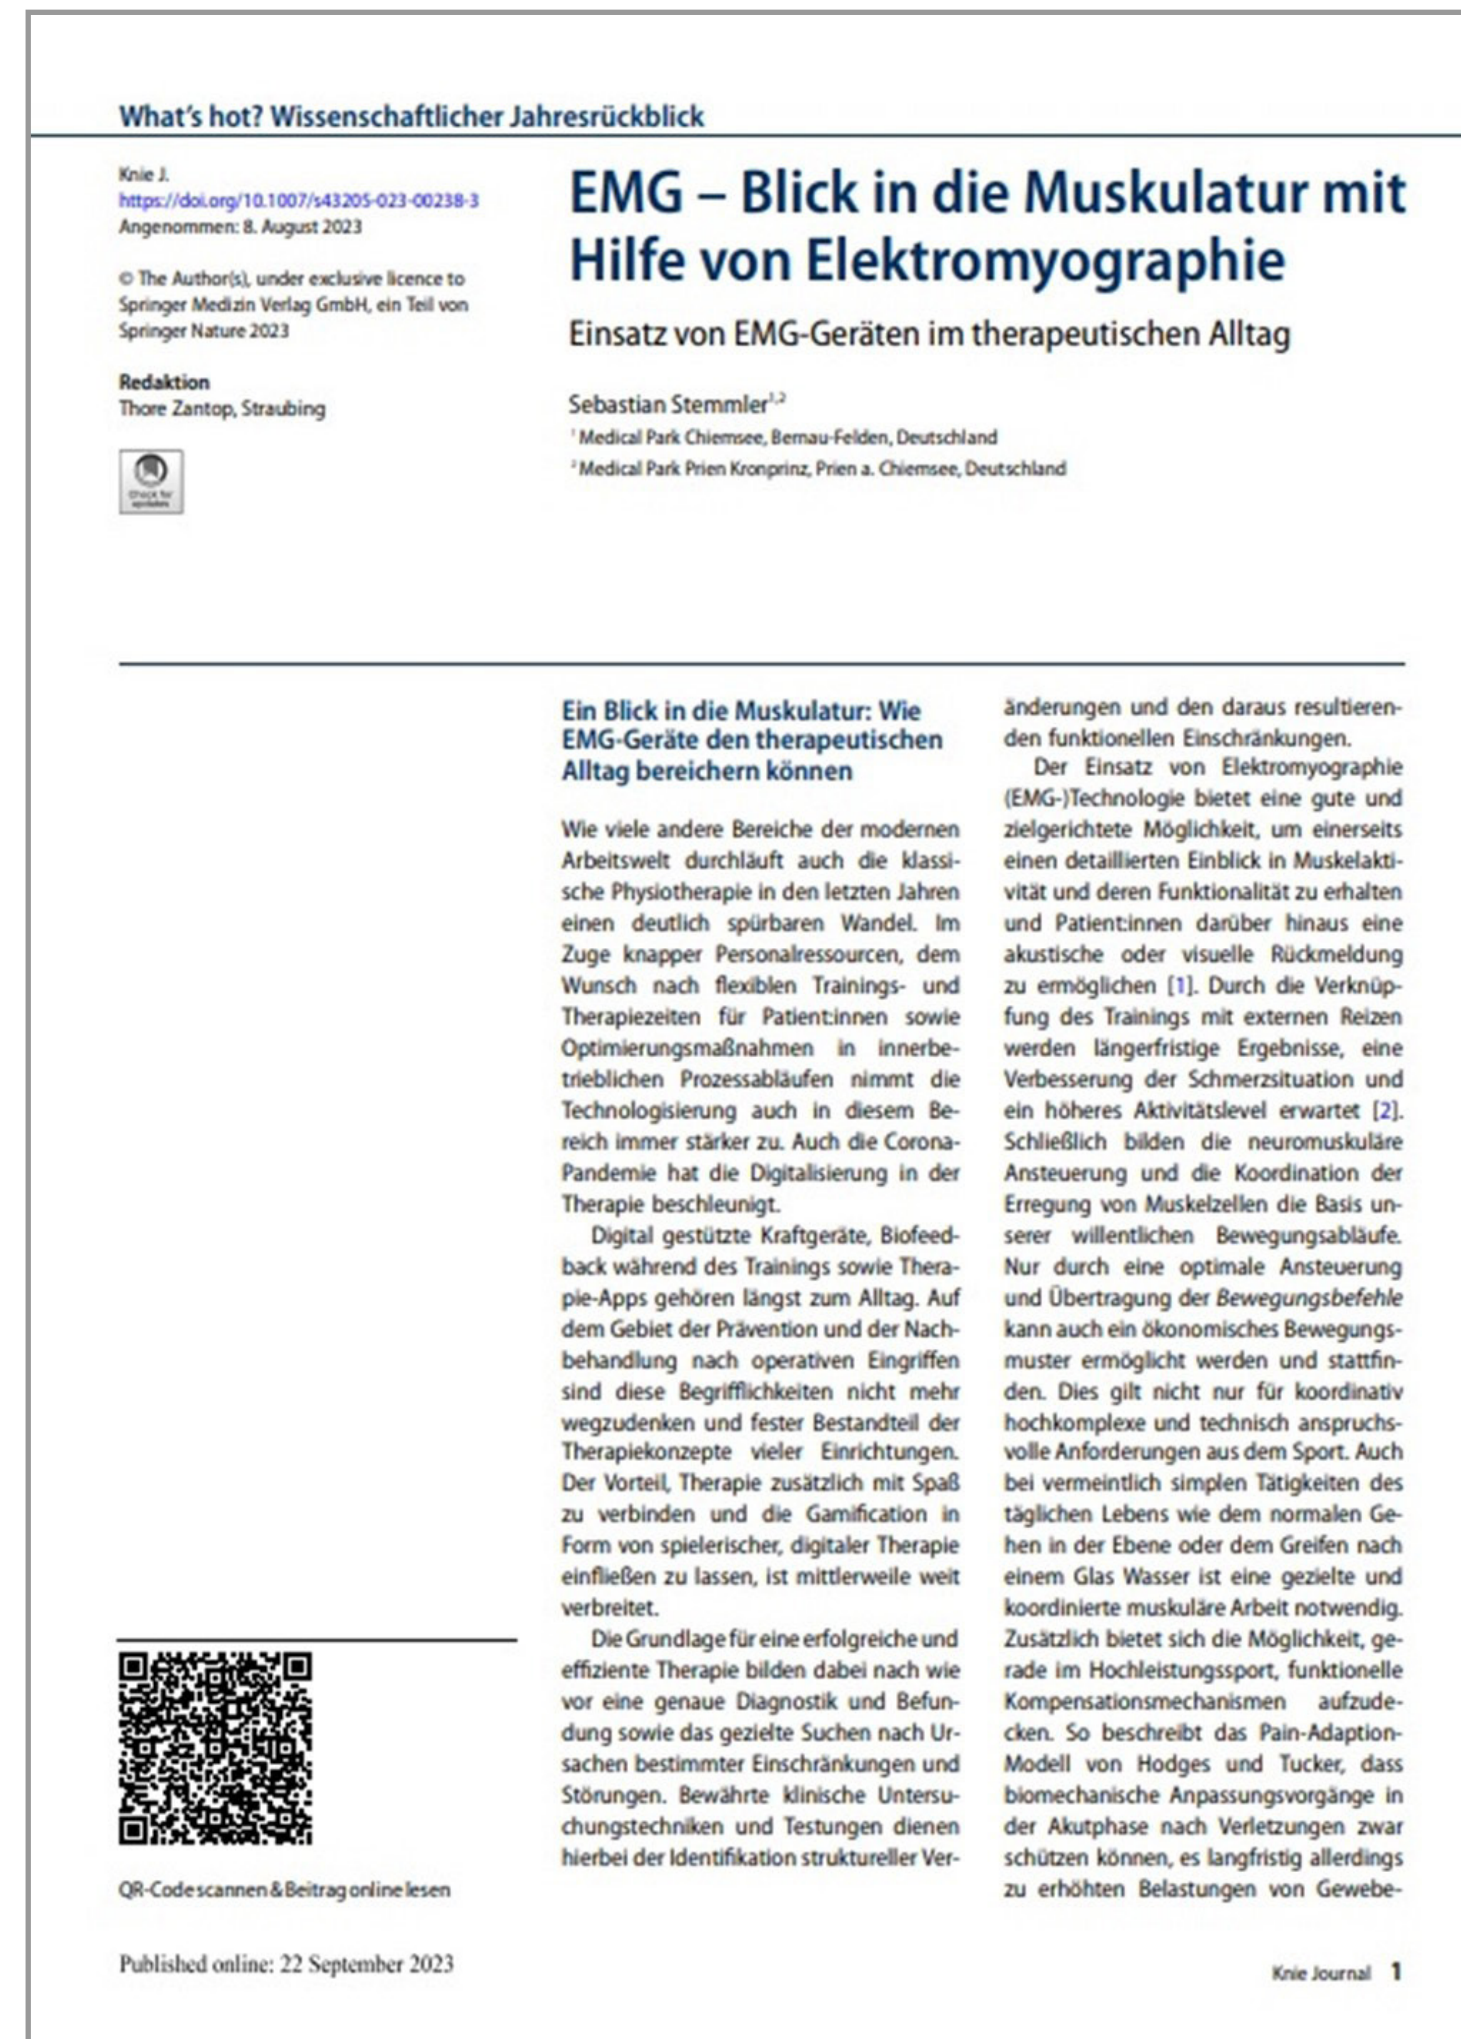

sEMG may be a valuable addition to the basic examination of patients following SCI (functional and neurological scales). However, muscle fatigue, which is observed in patients with SCI after DPT more than after RAGT, may pose a challenge to conducting the sEMG test. Knee joint kinematics is an important parameter for evaluating patients undergoing RAGT which has the potential to alleviate spasticity in patients with incomplete SCI.

Abstract. Rehabilitation of patients with impaired grip functions involves standard exercise that should be repeated in a predefined sequence. They are aimed to gradually improve patients' ability to grip and operate objects used in daily life. Rehabilitation robots, employing surface EMG (sEMG) as a diagnostic and feedback signal may be used to support these exercises and trace the rehabilitation progress. However, to properly employ exercise regimen, information about what force should be used to hold and operate various objects is needed. This work is focused on finding the correlation between the value of sEMG signal and the force required to grip a particular object. Calibration plots obtained that way will reduce the need for additional equipment, such as specialized gloves, and at the same time provide information needed for better exercise protocols.

Keywords: EMG · mapping · force · pinch meter · robotics.

1 Introduction

SEMG (Surface Electromyography) is a non-invasive measurement technique that facilitates analysis of skeletal muscle activity by recording electrical signals generated by muscle fibers during contractions. The method involves placing electrodes on the skin surface, over the muscles being studied. SEMG allows for the assessment of muscle activation timing, intensity, and coordination.

SEMG has many applications in various fields such as sports science, rehabilitation, ergonomics, and neurophysiology (see, e.g. the review in [6]). It is used to study, e.g., muscle function, movement, and fatigue. SEMG can provide valuable information about muscle activity during different activities, such as walking, running, or weightlifting.

The results of SEMG measurements are used in a variety of ways, including understanding the mechanisms of muscle contractions, monitoring the progression of muscle disease treatment, assessing the impact of therapy and rehabilitation on muscle function, and analyzing movement and ergonomic work [1–3]. The

3.2.2. EMG mapping technique for pinch meter robot extension.

Goal:

In this work authors concentrate on exercises consisting in using a key-type handle, aiming at improving gripping and turning motor skills. This type of a handle may represent various objects, such as a lock key, TV remote, a credit card, a fork, a medium-sized cup, a smart-phone, a small or large plate.

Conclusion:

The proposed calibration workstation, consisting of a simple force measurement module with a trapezoidal grip overlay provides sufficient hand contact for a scissor grip.

Abstract: In this paper, surface electromyography (sEMG) is used to gather the activation neural signal from muscles during an indoor rowing exercise. The exercise was performed by professional athletes and amateur non-athletes. The data acquisition and processing are described to obtain a set of parameters: number of cycles, average cycle time, cycle time standard deviation, fatigue time, muscle activation time, and muscle energy. These parameters are used to draw conclusions on common non-athletes’ mistakes during exercise for better training advice and a way of statistically distinguishing an athlete from a non-athlete.

1. Introduction

Nowadays, one can notice an increased willingness of people to take care of their personal physical development and practice amateur sports. Additionally, amateurs often use various types of equipment and gadgets to help them exercise. Wearable devices measuring some physical or physiological quantity can enhance the process of sensing and provide better coaching advice. The application of science and technology may offer a significant competitive advantage [1]. Wearable technology holds immense potential in the near future for being able to flatten the cost curve of healthcare [2].

Indoor rowing activates multiple muscles and body parts, especially arms (biceps), legs (quadriceps), and stomach muscles. Usually, the indoor rowing machine is equipped with an air resistance mechanism and a sensor that recalculates an applied pulling force. The performance is measured according to this force in each stroke. This device and its internal sensors can be used as research parameters on exercising behaviors [3,4].

In this research, the muscle activation time is measured and processed. Muscle activation time is frequently used to determine the correctness of performed tasks or to identify limits [5–7]. Muscle activation can be used to determine muscle fatigue [8–10] or can be an indicator of an illness for diagnostic purpose [11–13]. Usually, this is performed using surface electromyography (sEMG), but recent studies show the possibility of utilizing other sensors, such as an inertial measurement unit (IMU) [14–16], or contactless options with use of motion capture, computer vision, and deep learning pose estimation [17–19].

sEMG is capable of detecting muscle contraction time and strength for diagnosis and rehabilitation purposes [20,21]. Despite medical purposes and rehabilitation, sEMG is used to investigate novel approaches to human–robot interaction (HRI). Detecting muscle contractions with sEMG can be used for hand gesture recognition [22,23] or for direct manipulator control [24–26].

Sensors **2024**, *24*, 1964. <https://doi.org/10.3390/s24061964> <https://www.mdpi.com/journal/sensors>

3.2.3. Surface Electromyography Data Analysis for Evaluation of Physical Exercise Habits between Athletes and Non-Athletes during Indoor Rowing.

Goal:

The aim of this paper is to analyze surface electromyography (sEMG) data from the biceps and quadriceps during indoor rowing. It aims to identify performance parameters and common errors, distinguish between athletes and non-athletes, and recognize individuals with sports potential. Ultimately, the study seeks to provide insights into muscle activation patterns for improved coaching and training recommendations.

Conclusion:

The conclusion of this research highlights the effectiveness of measuring individual sports activities and identifies key findings: professionals outperform amateurs, fatigue affects muscle strength over time, and the research offers a method for quantifying these phenomena. By utilizing muscle activation times and local extrema positions, along with indicators of fatigue such as changes in cycle amplitude and time, this study provides valuable insights for coaching and training recommendations during exercise.
